## Abstract

This paper deals with the ill-posed backwards heat equation. To do this, we propose the controllability method. The point of view adopted, which consists in interpreting the state equation as an inverse problem, allows us to obtain a decoupled and strong singular optimality system for the optimal control-state pair, but also to propose an existence criteria for a regular solution of the backwards heat equation. It is important to note that this results are obtained without recourse to a Slater-type assumption, an assumption to which many analyses have had to recourse.

**Keywords:** Singular distributed systems, Optimal control, Ill-posed backwards heat equation, Controllability, Inverse Problem.

## 1 Introduction

Let us consider an open and bounded subset  $\Omega$  of  $\mathbb{R}^n$ ,  $n \in \mathbb{N}^*$ , of boundary  $\Gamma$ , twice continuously differentiable, with  $\Omega$  locally on one side only of  $\Gamma$ ; that is to say that  $\bar{\Omega}$  is a variety with a boundary of class  $\mathcal{C}^2$ .

For  $T > 0$ , we denote  $Q = \Omega \times (0, T)$ ,  $\Sigma = \Gamma \times (0, T)$ , and  $\mathcal{U}_{ad}$  a closed and non-empty convex of  $L^2(Q)$ .

For  $v \in L^2(Q)$ , we on consider the following problem

---

\*bylli.guel@uv.bf / 01 BV 30770 Ouagadougou 01, Burkina Faso

$$\begin{cases} \frac{\partial z}{\partial t} - \Delta z = v & \text{in } Q, \\ z = 0 & \text{on } \Sigma, \\ z(\cdot, T) = 0 & \text{in } \Omega, \end{cases} \quad (1)$$

being interested by the evolution, in  $\Omega$  and at a time  $t \in (0, T)$ , of the temperature  $z$  knowing its value at the final time  $T$ .

It is well known that problem (1), so called the ill-posed backwards heat equation, does not admits solution for any initial data.

So we consider, a priori, pairs  $(v, z) \in (L^2(Q))^2$  satisfying (1), saying that such pairs constitute the set of control-state pairs.

A control-state pair  $(v, z)$  for (1) will be said admissible if

$$v \in \mathcal{U}_{ad};$$

and we will denote  $(v, z) \in \mathcal{A}$ , designating by  $\mathcal{A}$  the set of optimal control-state pairs.

Supposing that the set  $\mathcal{A}$  of admissible control-state pairs is non-empty, we introduce the cost function

$$J(v, z) = \frac{1}{2} \|z - z_d\|_{L^2(Q)}^2 + \frac{N}{2} \|v\|_{L^2(Q)}^2,$$

where  $z_d \in L^2(Q)$  and  $N > 0$ .

Then, we are interested in the control problem which consists in finding the control-state pair

$$(u, y) \in \mathcal{A}_{ad} : \quad J(u, y) = \inf_{(v, z) \in \mathcal{A}_{ad}} J(v, z). \quad (2)$$

The following result is then immediate

**Theorem 1.** *The optimal control problem (2) admits a unique solution  $(u, y)$ , called the optimal control-state pair.*

*Proof.* Due to its structure, the cost functional  $J$  is coercive, strictly convex and lower semi-continuous. From where, with the non-vacuity assumption of the closed convex set of admissible control-state pairs  $\mathcal{A}$ , we can conclude to existence and unicity of the optimal control-state pair  $(u, y)$ .  $\square$

Hence, one can establish, (cf. [6]), using the first-order Euler-Lagrange optimality condition, that the optimal control-state pair  $(u, y)$  is characterized by

$$(y - z_d, z - y)_{L^2(Q)} + N(u, v - u)_{L^2(Q)} \geq 0, \quad \forall (v, z) \in \mathcal{A}.$$

We now focus on the characterization of the optimal pair  $(u, y)$  through a strong and decoupled singular optimality system.

A classic method to do so is the penalization method introduced by J. L. Lions in [6]. This one consists of approaching the optimal control-state pair  $(u, y)$  by a penalized problem. More precisely, for  $\varepsilon > 0$ , we define the penalized cost function

$$J_\varepsilon(v, z) = J(v, z) + \frac{1}{\varepsilon} \left\| \frac{\partial z}{\partial t} - \Delta z - v \right\|_{L^2(Q)}^2.$$

We then establish that the optimal control-state pair  $(u_\varepsilon, z_\varepsilon)$  corresponding to this last cost function converges towards the optimal control-state pair  $(u, y)$ . We therefore have a theoretical approximation process for the optimal pair  $(u, y)$ . Thanks to the first-order Euler-Lagrange optimality condition, we characterize the approached optimal control-state pair  $(u_\varepsilon, y_\varepsilon)$  by a system of variational inequalities which we interpret as an approached optimality system after introducing the approached adjoint state

$$p_\varepsilon = -\frac{1}{\varepsilon} \left( \frac{\partial y_\varepsilon}{\partial t} - \Delta y_\varepsilon - u_\varepsilon \right).$$

The main step of this technique is the use of the *a priori* estimation method to obtain a strongly decoupled optimality system by passing to the limit in the approached optimality system. But this final step requires the Slater-type assumption that

$$\text{“the set of admissible controls } \mathcal{U}_{ad} \text{ is of non empty interior in } L^2(Q)\text{”}. \quad (3)$$

But in many situations, the Slater-type assumption does not hold; for example in the case

$$\mathcal{U}_{ad} = (L^2(Q))^+ = \{v \in L^2(Q) : v \geq 0\}.$$

It therefore appears relevant to know how to do without this unrealistic assumption.

For this purpose, R. Dorville, O. Nakoulima et A. Omrane propose in [1], the notion of least regrets control, applied to a regularized elliptic state equation with missing data. An approach that allows them to characterize the least regrets control  $u^\gamma$  through a strongly decoupled singular optimality system. This, certainly without recourse to the Slater-type assumption (3), but to the detriment of the final condition

$$y^\gamma(\cdot, T) = 0 \quad \text{in } \Omega.$$

That is to say, more precisely, that the state  $y^\gamma$  associated with the least regrets control  $u^\gamma$  is such that, in all generality,

$$y^\gamma(\cdot, T) \neq 0 \quad \text{in } \Omega.$$

In response to this problem, the authors introduce the notion of zero-order corrector, which calls for the regularity assumption

$$y^\gamma(\cdot, T) \in H_0^1(\Omega) : \frac{\partial y^\gamma}{\partial t} \in L^2(Q). \quad (4)$$

This last one allows them to obtain the characterization specified below of the initial optimal control-state pair.

**Theorem 2** (cf. [1]). *The no-regret control  $u$  of the problem (1)(1)(2) is characterized by the unique  $\{u, y, \rho, p, \xi\}$  solution of the system:*

$$\left\{ \begin{array}{llll} Ly = u, & L\rho = 0, & L^*p = y - z_d + \rho, & L^*\xi = y \quad \text{in } Q, \\ y = 0, & \rho = 0, & p = 0, & \xi = 0, \quad \text{on } \Sigma, \\ y(0) = 0, & \rho(0) = \lambda(0) & & \text{in } \Omega, \\ & & p(T) = 0 & \xi(T) = 0 \quad \text{in } \Omega, \end{array} \right. \quad (5)$$

and we have the variational inequality

$$(p + Nu, v - u) \geq 0 \quad \forall v \in \mathcal{U}_{ad}, \quad (6)$$

with

$$\left| \begin{array}{l} L = \frac{\partial}{\partial t} - \Delta \quad \text{and} \quad L^* = -\frac{\partial}{\partial t} - \Delta \quad \text{its adjoint operator;} \\ u, y, p, \rho, \xi \in L^2([0, T[; L^2(\Omega))), \quad \lambda(0) \in L^2(\Omega). \end{array} \right.$$

Ultimately, the no-regret control thus obtained does not satisfy the final condition

$$y(\cdot, T) = 0 \text{ in } \Omega,$$

so that, in all generality, the problem remains, to the best of our knowledge, globally open.

We propose in this paper the controllability method for the analysis, without recourse to the Slater-type assumption (3), of the control problem of the ill-posed backwards heat equation. Note that this method has made it possible to propose in [2], [4], [3] and [5], an answer to the same question of the control, without recourse to (3), of control problems of ill-posed Cauchy system for elliptic, parabolic and hyperbolic operators.

The rest of this article is as follows. Section 2 is devoted to the announced interpretation of the initial problem as an inverse problem. We define there the so-called exact controllability problem which we approach, by density argument, by an equivalent problem (this one called the approached controllability problem). In Section 3, we return to the control problem (2), starting by regularized it based on the controllability results previously obtained. After established the convergence of the process in Section 3.1, then the approached optimality system in Section 3.2, we end in Section 3.3 with the optimality system for the initial control problem.

## 2 Controllability of the ill-posed backwards heat equation

In the present section, we introduce controllability viewpoint here proposed. Which consists, starting from the notion of controllability introduced by J.-L. Lions in [7, p. 222], in interpreting the initial state equation as an inverse problem (we also say a controllability problem).

We establish that, when it exists, the solution of the ill-posed backwards heat equation (1) is also, in the limit, a solution of the approached controllability problem. Which then makes it possible to establish a necessary and sufficient condition characterizing the existence of a regular solution to the problem (1).

We therefore interpret (1) as an inverse problem whose observation objective consists in the final condition

$$z(\cdot, T) = 0 \text{ in } \Omega.$$

More precisely, we consider the following problem

$$\begin{cases} \frac{\partial y}{\partial t} - \Delta y = v & \text{in } Q, \\ y = 0 & \text{on } \Sigma, \end{cases}$$

posing the problem of finding  $y_0 \in L^2(\Omega)$  such that if

$$\begin{cases} \frac{\partial y}{\partial t} - \Delta y = v & \text{in } Q, \\ y = 0 & \text{on } \Sigma, \\ y(\cdot, 0) = y_0 & \text{in } \Omega, \end{cases} \tag{7}$$

then

$$y(\cdot, T) = 0 \text{ in } \Omega. \tag{8}$$

We say that (7)(8) constitutes an exact controllability problem associated with the ill-posed backward heat equation (1).

**Remark 1.** *The controllability problem is well defined. Indeed, it is well known that for any  $v \in L^2(Q)$  and  $y_0 \in L^2(\Omega)$ , (7) is well posed in the sense of Hadamard. That is to say that it admits a unique solution*

$$y(v, y_0) \in \mathbb{V} := L^2(0, T; H_0^1(\Omega)) \cap \mathcal{C}([0, T]; L^2(\Omega))$$

*which depends continuously on the data. We deduce from this that, after possible modification on a set of zero measure, the solution  $y(v, y_0)$  of (7) merges with a continuous function from  $(0, T)$  to  $L^2(\Omega)$ .*

*Thus we can indeed speak of the final value  $y(\cdot, T; v, y_0)$  of  $y(v, y_0)$  in  $\Omega$ .*

**Remark 2.** *Let us denote*

- $y^v$  the unique solution of (7);
- $y_0^v \in \mathbb{V} \subset L^2(Q)$  that of

$$\begin{cases} \frac{\partial y_0^v}{\partial t} - \Delta y_0^v = v & \text{in } Q, \\ y_0^v = 0 & \text{on } \Sigma, \\ y_0^v(\cdot, 0) = 0 & \text{in } \Omega, \end{cases}$$

- and  $y^0 \in \mathbb{V} \subset L^2(Q)$  that of

$$\begin{cases} \frac{\partial y^0}{\partial t} - \Delta y^0 = 0 & \text{in } Q, \\ y^0 = 0 & \text{on } \Sigma, \\ y^0(\cdot, 0) = y_0 & \text{in } \Omega. \end{cases} \tag{9}$$

*Then we have that the mapping*

$$(v, y_0) \longmapsto y^v = y_0^v + y^0,$$

*is linear and continuous from  $L^2(Q) \times L^2(Q)$  to  $\mathbb{V} \subset L^2(Q)$ .*

*We deduce that the exact controllability problem (7)(8) is equivalent to the following*

$$\begin{cases} \text{find } y_0 \in L^2(\Omega) \text{ such that:} \\ \text{if } y^0 \text{ is solution of (9), then} \\ y^0(\cdot, T) = -y_0^v(\cdot, T) & \text{in } \Omega. \end{cases} \tag{10}$$

We approach the exact controllability problem (10) by density argument as specified below.

**Proposition 1.** *When the initial data  $y_0$  traverses  $L^2(\Omega)$ , the set*

$$E = \{y^0(\cdot, T) ; y_0 \in L^2(\Omega)\},$$

*described by the final values of the solution  $y^0$  of (9), is dense in  $L^2(\Omega)$ .*

*Proof.* It is clear that the set  $E$  constitute a vector subspace of  $L^2(\Omega)$ . From where, by the Hahn-Banach Theorem,  $E$  is dense in  $L^2(\Omega)$  if and only if  $E^\perp = \{0\}$ .

Let us consider  $k \in E^\perp$ ; so we have

$$\forall y_0 \in L^2(\Omega), \quad (k, y^0(\cdot, T))_{L^2(\Omega)} = 0.$$

But it comes from (9) that, for any test function  $\varphi \in \mathcal{D}(Q)$ , we have:

$$\begin{aligned} \left( \frac{\partial y^0}{\partial t} - \Delta y^0, \varphi \right)_{L^2(Q)} = 0 &\iff \left( \frac{\partial y^0}{\partial t}, \varphi \right)_{L^2(Q)} - (\Delta y^0, \varphi)_{L^2(Q)} = 0 \\ &\iff (y^0(\cdot, T), \varphi(\cdot, T))_{L^2(\Omega)} - (y_0, \varphi(\cdot, 0))_{L^2(\Omega)} \\ &\quad - \left( y^0, \frac{\partial \varphi}{\partial t} \right)_{L^2(Q)} - (y^0, \Delta \varphi)_{L^2(Q)} + \left( y^0, \frac{\partial \varphi}{\partial \nu} \right)_{L^2(\Sigma)} \\ &\quad - \left( \frac{\partial y^0}{\partial \nu}, \varphi \right)_{L^2(\Sigma)} = 0 \end{aligned}$$

*i.e.*

$$\begin{aligned} (y^0(\cdot, T), \varphi(\cdot, T))_{L^2(\Omega)} - (y_0, \varphi(\cdot, 0))_{L^2(\Omega)} - \left( y^0, \frac{\partial \varphi}{\partial t} \right)_{L^2(Q)} \\ - (y^0, \Delta \varphi)_{L^2(Q)} - \left( \frac{\partial y^0}{\partial \nu}, \varphi \right)_{L^2(\Sigma)} = 0. \end{aligned} \tag{11}$$

Choosing  $\varphi$ , in the above, such that

$$\begin{cases} -\frac{\partial \varphi}{\partial t} - \Delta \varphi = 0 & \text{in } Q, \\ \varphi = 0 & \text{on } \Sigma, \\ \varphi(\cdot, T) = k & \text{in } \Omega, \end{cases} \tag{12}$$

it comes that (11) is equivalent to

$$(k, y^0(\cdot, T))_{L^2(\Omega)} - (y_0, \varphi(\cdot, 0))_{L^2(\Omega)} = 0, \tag{13}$$

where

$$k \in E^\perp \iff (k, y^0(\cdot, T))_{L^2(\Omega)} = 0.$$

Thus (13) becomes

$$\forall y_0 \in L^2(\Omega), \quad (y_0, \varphi(\cdot, 0))_{L^2(\Omega)} = 0. \tag{14}$$

But we can still choose, in (14),  $y_0 = \varphi(\cdot, 0)$  in  $\Omega$ , and then it follows

$$\|\varphi(\cdot, 0)\|_{L^2(\Omega)}^2 = 0 \quad \text{i.e.} \quad \varphi(\cdot, 0) = 0 \quad \text{in } \Omega.$$

Which brings, with (12), that  $\varphi$  is solution of

$$\begin{cases} -\frac{\partial \varphi}{\partial t} - \Delta \varphi = 0 & \text{in } Q, \\ \varphi = 0 & \text{on } \Sigma, \\ \varphi(\cdot, 0) = 0 & \text{in } \Omega, \end{cases}$$

that is to say that  $\varphi \equiv 0$  and consequently that

$$\varphi(\cdot, T) = k = 0 \quad \text{in } \Omega.$$

From where we deduce that  $E^\perp = \{0\}$  and therefore that  $E$  is dense in  $L^2(\Omega)$ .  $\square$

The following result is then immediate.

**Corollary 1.** *For any  $\varepsilon > 0$  and  $\kappa \in L^2(\Omega)$ , there exists  $y_{0\varepsilon} \in L^2(\Omega)$  such that the solution  $y_\varepsilon^0 \in \mathbb{V}$  of*

$$\begin{cases} \frac{\partial y_\varepsilon^0}{\partial t} - \Delta y_\varepsilon^0 = v & \text{in } Q, \\ y_\varepsilon^0 = 0 & \text{on } \Sigma, \\ y_\varepsilon^0(\cdot, 0) = y_{0\varepsilon} & \text{in } \Omega, \end{cases} \quad (15)$$

also satisfies

$$\|y_\varepsilon^0(\cdot, T) - \kappa\|_{L^2(\Omega)} < \varepsilon.$$

From which it also follows that

**Corollary 2.** *Given  $v \in L^2(Q)$  and  $\varepsilon > 0$ , there exists  $y_{0\varepsilon} \in L^2(\Omega)$  such that the solution  $y_\varepsilon^v \in \mathbb{V}$  of*

$$\begin{cases} \frac{\partial y_\varepsilon^v}{\partial t} - \Delta y_\varepsilon^v = v & \text{in } Q, \\ y_\varepsilon^v = 0 & \text{on } \Sigma, \\ y_\varepsilon^v(\cdot, 0) = y_{0\varepsilon} & \text{in } \Omega, \end{cases} \quad (16)$$

satisfies

$$\|y_\varepsilon^v(\cdot, T)\|_{L^2(\Omega)} < \varepsilon.$$

*Proof.* Let  $v \in L^2(Q)$  and  $\varepsilon > 0$ . We know that there exists a unique  $y_0^v \in \mathbb{V}$ , almost everywhere equal to a continuous mapping from  $(0, T)$  to  $L^2(\Omega)$ , solution of

$$\begin{cases} \frac{\partial y_0^v}{\partial t} - \Delta y_0^v = v & \text{in } Q, \\ y_0^v = 0 & \text{on } \Sigma, \\ y_0^v(\cdot, 0) = 0 & \text{in } \Omega. \end{cases}$$

It follows that, with Corollary 1, there exists  $y_{0\varepsilon} \in L^2(\Omega)$  such that the solution  $y_\varepsilon^0 \in \mathbb{V}$  of (15) satisfies

$$\|y_\varepsilon^0(\cdot, T) - (-y_0^v(\cdot, T))\|_{L^2(\Omega)} < \varepsilon.$$

Which allows us to conclude that  $y_\varepsilon^v = (y_0^v + y_\varepsilon^0) \in \mathbb{V}$  is unique solution of (16), with

$$\|y_\varepsilon^v(\cdot, T)\|_{L^2(\Omega)} = \|y_0^v(\cdot, T) + y_\varepsilon^0(\cdot, T)\|_{L^2(\Omega)} < \varepsilon.$$

$\square$

More over, we have the following theorem, characterizing the existence of a regular solution to the ill-posed backwards heat equation.

**Theorem 3.** *Let  $v \in L^2(Q)$ . The ill-posed backwards heat equation*

$$\begin{cases} \frac{\partial z}{\partial t} - \Delta z = v & \text{in } Q, \\ z = 0 & \text{on } \Sigma, \\ z(\cdot, T) = 0 & \text{in } \Omega, \end{cases} \quad (17)$$

*admits a regular solution  $z \in \mathbb{V}$  if and only if the sequence  $(y_{0_\varepsilon})_\varepsilon$  is bounded in  $L^2(\Omega)$ .*

*Proof.* 1. Let  $\varepsilon > 0$ . From Corollary 1, there exists  $y_{0_\varepsilon} \in L^2(\Omega)$  such as  $y_\varepsilon^v \in \mathbb{V}$  is solution of

$$\begin{cases} \frac{\partial y_\varepsilon^v}{\partial t} - \Delta y_\varepsilon^v = v & \text{in } Q, \\ y_\varepsilon^v = 0 & \text{on } \Sigma, \\ y_\varepsilon^v(\cdot, 0) = y_{0_\varepsilon} & \text{in } \Omega, \end{cases} \quad (18)$$

with the estimate

$$\|y_\varepsilon^v(\cdot, T)\|_{L^2(\Omega)} < \varepsilon.$$

Then, we generate sequences

$$(y_{0_\varepsilon})_\varepsilon \subset L^2(\Omega) \quad \text{and} \quad (y_\varepsilon^v)_\varepsilon \subset \mathbb{V}.$$

Assuming that the sequence  $(y_{0_\varepsilon})_\varepsilon$  is bounded in  $L^2(\Omega)$ . Therefore, it follows that, the homogeneous Dirichlet problem (18) for the heat equation being well-posed, the sequence  $(y_\varepsilon^v)_\varepsilon$  is bounded in  $\mathbb{V}$ , and therefore also in  $L^2(Q)$ .

So we can extract from  $(y_{0_\varepsilon})_\varepsilon$  and  $(y_\varepsilon^v)_\varepsilon$  subsequences, still denoted in the same way, which converge weakly in  $L^2(\Omega)$  and  $\mathbb{V}$ , respectively.

So that, there exists  $y_0 \in L^2(\Omega)$  and  $y^v \in \mathbb{V}$ , such as

$$\begin{cases} y_{0_\varepsilon} \longrightarrow y_0 & \text{weakly in } L^2(\Omega), \\ y_\varepsilon^v \longrightarrow y^v & \text{weakly in } \mathbb{V}. \end{cases}$$

Thus we have on the one hand, that

$$\|y_\varepsilon^v(\cdot, T)\|_{L^2(\Omega)} < \varepsilon \quad \text{and} \quad y_\varepsilon^v \longrightarrow y^v \quad \text{weakly in } \mathbb{V}$$

imply,  $y_\varepsilon^v$  being almost everywhere equal to a continuous mapping from  $(0, T)$  to  $L^2(\Omega)$ , that

$$y^v(\cdot, T) = 0 \quad \text{in } \Omega. \quad (19)$$

On the other hand, we have for any  $\varphi \in \mathcal{C}(Q)$  that:

$$\begin{aligned} \frac{\partial y_\varepsilon^v}{\partial t} - \Delta y_\varepsilon^v = v \text{ in } Q &\iff \left( \frac{\partial y_\varepsilon^v}{\partial t} - \Delta y_\varepsilon^v, \varphi \right)_{L^2(Q)} = (v, \varphi)_{L^2(Q)} \\ &\iff (y_\varepsilon^v(\cdot, T), \varphi(\cdot, T))_{L^2(\Omega)} - (y_{0\varepsilon}, \varphi(\cdot, 0))_{L^2(\Omega)} \\ &\quad - \left( y_\varepsilon^v, \frac{\partial \varphi}{\partial t} \right)_{L^2(Q)} - (y_\varepsilon^v, \Delta \varphi)_{L^2(Q)} - \left( \frac{\partial y_\varepsilon^v}{\partial \nu}, \varphi \right)_{L^2(\Sigma)} \\ &= (v, \varphi)_{L^2(Q)}, \end{aligned}$$

so, by passing to the limit,

$$\begin{aligned} &(y^v(\cdot, T), \varphi(\cdot, T))_{L^2(\Omega)} - (y_0, \varphi(\cdot, 0))_{L^2(\Omega)} - \left( y^v, \frac{\partial \varphi}{\partial t} \right)_{L^2(Q)} \\ &\quad - (y^v, \Delta \varphi)_{L^2(Q)} - \left( \frac{\partial y^v}{\partial \nu}, \varphi \right)_{L^2(\Sigma)} = (v, \varphi)_{L^2(Q)} \\ &\iff (y^v(\cdot, 0) - y_0, \varphi(\cdot, 0))_{L^2(\Omega)} + \left( \frac{\partial y^v}{\partial t} - \Delta y^v, \varphi \right)_{L^2(Q)} \\ &\quad - \left( y^v, \frac{\partial \varphi}{\partial \nu} \right)_{L^2(\Sigma)} = (v, \varphi)_{L^2(Q)}. \end{aligned}$$

This last equality being valid for any  $\varphi \in \mathcal{C}(Q)$ , it follows that

$$\left\{ \begin{array}{l} \frac{\partial y^v}{\partial t} - \Delta y^v = v \quad \text{in } Q, \\ y^v = 0 \quad \text{on } \Sigma, \\ y^v(\cdot, 0) = y_0 \quad \text{in } \Omega, \end{array} \right.$$

which implies, with (19), that

$$\left\{ \begin{array}{l} \frac{\partial y^v}{\partial t} - \Delta y^v = v \quad \text{in } Q, \\ y^v = 0 \quad \text{on } \Sigma, \\ y^v(\cdot, T) = 0 \quad \text{in } \Omega, \end{array} \right.$$

that is to say that  $y^v \in \mathbb{V}$  is solution of the ill-posed backwards heat equation (17).

2. Now, let assume that the ill-posed backwards heat equation (17) admits a regular solution  $z \in \mathbb{V}$ .

Then, since  $z \in \mathbb{V}$  implies that  $z$  is almost everywhere equal to a continuous function from  $(0, T)$  to  $L^2(\Omega)$ , we can, after possible modification on a set of zero measure, to speak of the initial value  $z(\cdot, 0) \in L^2(\Omega)$ .

Then, by choosing, for any  $\varepsilon > 0$ ,

$$y_{0\varepsilon} = z(\cdot, 0) \quad \text{in } \Omega,$$

we obtain that the sequence  $(y_{0\varepsilon})_\varepsilon$ , since constant, is bounded in  $L^2(\Omega)$ .

□

### 3 The optimal control problem

Let us start by recalling that we are here interested in the control problem of the ill-posed backwards heat equation. That is to say, more precisely, that for  $v, z \in L^2(Q)$  satisfying

$$\begin{cases} \frac{\partial z}{\partial t} - \Delta z = v & \text{in } Q, \\ z = 0 & \text{on } \Sigma, \\ z(\cdot, T) = 0 & \text{on } \Omega, \end{cases} \quad (20)$$

on pose

$$J(v, z) = \frac{1}{2} \|z - z_d\|_{L^2(Q)}^2 + \frac{N}{2} \|v\|_{L^2(Q)}^2, \quad (21)$$

s'intéressant au problème de contrôle

$$\inf \{ J(v, z); (v, z) \in \mathcal{A} \}. \quad (22)$$

As underlined in the introduction, the optimal control problem (20)(21)(22) admits a unique solution  $(u, y)$  whose characterization, via a strong and decoupled singular optimality system, and this without using the Slater-type assumption (3), is the main objective.

To do so, starting from the non-vacuity assumption of the set of admissible control-state pairs, and using the results previously obtained, we have for any  $v \in L^2(Q)$  and  $\varepsilon > 0$  that there exists

$$y_{0\varepsilon} \in L^2(\Omega) \quad \text{and} \quad y_\varepsilon^v \in \mathbb{V}$$

such that

$$\begin{cases} \frac{\partial y_\varepsilon^v}{\partial t} - \Delta y_\varepsilon^v = v & \text{in } Q, \\ y_\varepsilon^v = 0 & \text{on } \Sigma, \\ y_\varepsilon^v(\cdot, 0) = y_{0\varepsilon} & \text{in } \Omega, \end{cases}$$

with the estimate

$$\|y_\varepsilon^v(\cdot, T)\|_{L^2(\Omega)} < \varepsilon.$$

Assuming that the optimal solution  $(u, y)$  for (20)(21)(22) is such that  $y(\cdot, 0) \in L^2(\Omega)$ , we introduce the functional

$$J_\varepsilon(v) = \frac{1}{2} \|y_\varepsilon^v - z_d\|_{L^2(Q)}^2 + \frac{N}{2} \|v\|_{L^2(Q)}^2 + \frac{1}{2\varepsilon} \|y_{0\varepsilon} - y(\cdot, 0)\|_{L^2(\Omega)}^2,$$

begin interested in the control problem

$$\inf \{ J_\varepsilon(v); v \in \mathcal{U}_{ad} \}. \quad (23)$$

The following result is then immediate.

**Proposition 2.** *For any  $\varepsilon > 0$ , the control problem (23) admits a unique solution: the approached optimal control-state pair  $\bar{u}_\varepsilon$ .*

### 3.1 Convergence of the method

Let  $\varepsilon > 0$ . For the approached optimal control, the results previously obtained lead to the existence of

$$\bar{y}_{0\varepsilon} \in L^2(\Omega) \quad \text{and} \quad \bar{y}_\varepsilon \in \mathbb{V}$$

satisfying

$$\left\{ \begin{array}{l} \frac{\partial \bar{y}_\varepsilon}{\partial t} - \Delta \bar{y}_\varepsilon = \bar{u}_\varepsilon \quad \text{in } Q, \\ \bar{y}_\varepsilon = 0 \quad \text{on } \Sigma, \\ \bar{y}_\varepsilon(\cdot, 0) = \bar{y}_{0\varepsilon} \quad \text{in } \Omega, \end{array} \right. \quad (24)$$

and the estimate

$$\|\bar{y}_\varepsilon(\cdot, T)\|_{L^2(\Omega)} < \varepsilon,$$

with

$$J_\varepsilon(\bar{u}_\varepsilon) \leq J_\varepsilon(v), \quad \forall v \in \mathcal{U}_{ad}.$$

In particular

$$J_\varepsilon(\bar{u}_\varepsilon) \leq J_\varepsilon(u), \quad (25)$$

where  $u$  is the optimal control-state pair of (20)(21)(22).

We have in fact that  $J_\varepsilon(u)$  is independant of  $\varepsilon$ . Indeed, since the optimal state  $y$  associated with the optimal control  $u$  satisfies  $y(\cdot, 0) \in L^2(\Omega)$ , we obtain by posing  $y_{0\varepsilon}^* = y(\cdot, 0)$  that  $y$  satisfies

$$\left\{ \begin{array}{l} \frac{\partial y}{\partial t} - \Delta y = u \quad \text{in } Q, \\ y = 0 \quad \text{on } \Sigma, \\ y(\cdot, 0) = y_{0\varepsilon}^* \quad \text{in } \Omega \end{array} \right.$$

with

$$y(\cdot, T) = 0 \quad \text{in } \Omega, \quad a \text{ fortiori} \quad \|y(\cdot, T)\|_{L^2(\Omega)} < \varepsilon.$$

It follows that  $J_\varepsilon(u)$  is defined, with

$$\begin{aligned} J_\varepsilon(u) &= \frac{1}{2} \|y - z_d\|_{L^2(Q)}^2 + \frac{N}{2} \|u\|_{L^2(Q)}^2 + \frac{1}{2\varepsilon} \|y_{0\varepsilon}^* - y(\cdot, 0)\|_{L^2(\Omega)}^2 \\ &= \frac{1}{2} \|y - z_d\|_{L^2(Q)}^2 + \frac{N}{2} \|u\|_{L^2(Q)}^2 = J(u, y). \end{aligned}$$

Hence (25) becomes

$$J_\varepsilon(\bar{u}_\varepsilon) \leq J_\varepsilon(u) = J(u, y), \quad (26)$$

and it follows that there exists constants  $C_i \in \mathbb{R}^*$  independant of  $\varepsilon$  such as

$$\|\bar{y}_\varepsilon\|_{L^2(Q)} \leq C_1, \quad \|\bar{u}_\varepsilon\|_{L^2(Q)} \leq C_2 \quad \text{and} \quad \|\bar{y}_{0\varepsilon}\|_{L^2(\Omega)} \leq C_3.$$

Then, we immediately deduce that there exists  $\hat{u} \in L^2(Q)$ ,  $\hat{y} \in L^2(Q)$  and  $\hat{y}_0 \in L^2(\Omega)$  such as

$$\left\{ \begin{array}{l} \bar{u}_\varepsilon \longrightarrow \hat{u} \quad \text{weakly in } L^2(Q), \\ \bar{y}_\varepsilon \longrightarrow \hat{y} \quad \text{weakly in } L^2(Q), \\ \bar{y}_{0\varepsilon} \longrightarrow \hat{y}_0 \quad \text{weakly in } L^2(\Omega). \end{array} \right.$$

But much more, (26) also implies

$$\|\bar{y}_{0\varepsilon} - y(\cdot, 0)\|_{L^2(\Omega)} \leq 2\varepsilon C_4, \quad (27)$$

which leads, since

$$\bar{y}_{0\varepsilon} \longrightarrow \hat{y}_0 \text{ weakly in } L^2(\Omega), \quad (28)$$

to

$$\hat{y}_0 = y(\cdot, 0) \text{ strongly in } \Omega. \quad (29)$$

Then it comes, with (24), that for any  $\varphi \in \mathcal{D}(Q)$ ,

$$\begin{aligned} \left( \frac{\partial \bar{y}_\varepsilon}{\partial t}, \varphi \right)_{L^2(Q)} - (\Delta \bar{y}_\varepsilon, \varphi)_{L^2(Q)} &= (\bar{u}_\varepsilon, \varphi)_{L^2(Q)} \\ \iff (\bar{y}_\varepsilon(\cdot, T), \varphi(\cdot, T))_{L^2(\Omega)} - (\bar{y}_{0\varepsilon}, \varphi(\cdot, 0))_{L^2(\Omega)} - \left( \bar{y}_\varepsilon, \frac{\partial \varphi}{\partial t} \right)_{L^2(Q)} \\ &\quad - (\bar{y}_\varepsilon, \Delta \varphi)_{L^2(Q)} - \left( \frac{\partial \bar{y}_\varepsilon}{\partial \nu}, \varphi \right)_{L^2(\Sigma)} = (\bar{u}_\varepsilon, \varphi)_{L^2(Q)}, \end{aligned}$$

which gives, passing to the limit,

$$\begin{aligned} (\hat{y}(\cdot, T), \varphi(\cdot, T))_{L^2(\Omega)} - (\hat{y}_0, \varphi(\cdot, 0))_{L^2(\Omega)} - \left( \hat{y}, \frac{\partial \varphi}{\partial t} \right)_{L^2(Q)} - (\hat{y}, \Delta \varphi)_{L^2(Q)} \\ - \left( \frac{\partial \hat{y}}{\partial \nu}, \varphi \right)_{L^2(\Sigma)} = (\hat{u}, \varphi)_{L^2(Q)} \\ \iff (\hat{y}(\cdot, 0) - \hat{y}_0, \varphi(\cdot, 0))_{L^2(\Omega)} + \left( \frac{\partial \hat{y}}{\partial t} - \Delta \hat{y}, \varphi \right)_{L^2(Q)} \\ - \left( \hat{y}, \frac{\partial \varphi}{\partial \nu} \right)_{L^2(\Sigma)} = (\hat{u}, \varphi)_{L^2(Q)}, \end{aligned}$$

i.e.

$$\left\{ \begin{array}{l} \frac{\partial \hat{y}}{\partial t} - \Delta \hat{y} = \hat{u} \quad \text{in } Q, \\ \hat{y} = 0 \quad \text{on } \Sigma, \\ \hat{y}(\cdot, 0) = \hat{y}_0 \quad \text{in } \Omega. \end{array} \right. \quad (30)$$

Moreover, the norm  $\|\cdot\|_{L^2(\Omega)}$  being continuous, *a fortiori* weakly continuous,

$$\bar{y}_\varepsilon \longrightarrow \hat{y} \text{ weakly in } L^2(Q) \quad \text{and} \quad \|\bar{y}_\varepsilon(\cdot, T)\|_{L^2(\Omega)} < \varepsilon$$

bring

$$\hat{y}(\cdot, T) = 0 \text{ in } \Omega. \quad (31)$$

Thus (30) and (31) allow to conclude that  $\hat{y} \in L^2(Q)$  satisfies

$$\left\{ \begin{array}{l} \frac{\partial \hat{y}}{\partial t} - \Delta \hat{y} = \hat{u} \quad \text{in } Q, \\ \hat{y} = 0 \quad \text{on } \Sigma, \\ \hat{y}(\cdot, T) = 0 \quad \text{in } \Omega, \end{array} \right.$$

noting that  $\hat{u} \in \mathcal{U}_{ad}$ , since  $\bar{u}_\varepsilon \in \mathcal{U}_{ad}$  and  $\mathcal{U}_{ad}$  is closed and therefore weakly closed: the control-state pair  $(\hat{u}, \hat{y})$  is admissible for (20)(21)(22), so that

$$J(u, y) \leq J(\hat{u}, \hat{y}). \quad (32)$$

On the other hand, passing (26) to the limit when  $\varepsilon \rightarrow 0$ , it comes  $J(\hat{u}, \hat{y}) \leq J(u, y)$ ; that is to say, with (32), that  $J(u, y) = J(\hat{u}, \hat{y})$ .

Then we conclude, by uniqueness of the optimal control-state pair  $(u, y)$ , that  $(\hat{u}, \hat{y}) = (u, y)$ , which ends up proving the following result.

**Proposition 3.** *For any  $\varepsilon > 0$ , the approach optimal control  $\bar{u}_\varepsilon$  and the associated state  $\bar{y}_\varepsilon$  satisfy*

$$\begin{cases} \bar{u}_\varepsilon \longrightarrow u & \text{weakly in } L^2(Q), \\ \bar{y}_\varepsilon \longrightarrow y & \text{weakly in } L^2(Q), \end{cases}$$

where  $(u, y)$  is the optimal control-state pair for (20)(21)(22).

We establish below that we actually have more: the strong convergence.

**Theorem 4.** *For any  $\varepsilon > 0$ , the approach optimal control  $\bar{u}_\varepsilon$  and the associated state  $\bar{y}_\varepsilon$  are such that, when  $\varepsilon \rightarrow 0$ ,*

$$\begin{cases} \bar{u}_\varepsilon \longrightarrow u & \text{strongly in } L^2(Q), \\ \bar{y}_\varepsilon \longrightarrow y & \text{strongly in } L^2(Q), \end{cases}$$

where  $(u, y)$  is the optimal control-state pair for (20)(21)(22).

*Proof.* From the results previously obtained above, we have that

$$\bar{u}_\varepsilon \longrightarrow u \quad \text{weakly in } L^2(Q), \quad (33)$$

$$\bar{y}_\varepsilon \longrightarrow y \quad \text{weakly in } L^2(Q), \quad (34)$$

and

$$J(u, y) = \lim_{\varepsilon \rightarrow 0} J_\varepsilon(\bar{u}_\varepsilon).$$

Where, from (27)(28) and (29), the last equality above can still be written

$$\|y - z_d\|_{L^2(Q)}^2 + N\|u\|_{L^2(Q)}^2 = \lim_{\varepsilon \rightarrow 0} \left( \|\bar{y}_\varepsilon - z_d\|_{L^2(Q)}^2 + N\|\bar{u}_\varepsilon\|_{L^2(Q)}^2 \right). \quad (35)$$

But then, the norm  $\|\cdot\|_{L^2(Q)}$  being continuous, *a fortiori* weakly lower semi-continuous, it comes, with (33) and (34), that

$$\begin{cases} \|y - z_d\|_{L^2(Q)}^2 & \leq \liminf_{\varepsilon \rightarrow 0} \|\bar{y}_\varepsilon - z_d\|_{L^2(Q)}^2, \\ \|u\|_{L^2(Q)}^2 & \leq \liminf_{\varepsilon \rightarrow 0} \|\bar{u}_\varepsilon\|_{L^2(Q)}^2. \end{cases}$$

From where it follows, with (35), that

$$\|y - z_d\|_{L^2(Q)}^2 = \lim_{\varepsilon \rightarrow 0} \|\bar{y}_\varepsilon - z_d\|_{L^2(Q)}^2, \quad (36)$$

and

$$\|u\|_{L^2(Q)}^2 = \lim_{\varepsilon \rightarrow 0} \|\bar{u}_\varepsilon\|_{L^2(Q)}^2. \quad (37)$$

Hence, since

$$\|\bar{y}_\varepsilon - y\|_{L^2(Q)}^2 = \|\bar{y}_\varepsilon - z_d\|_{L^2(Q)}^2 + \|y - z_d\|_{L^2(Q)}^2 - 2(\bar{y}_\varepsilon - z_d, y - z_d)_{L^2(Q)},$$

we conclude with (34) and (36) that

$$\lim_{\varepsilon \rightarrow 0} \|\bar{y}_\varepsilon - y\|_{L^2(Q)}^2 = 0 \quad i.e. \quad \bar{y}_\varepsilon \longrightarrow y \text{ strongly in } L^2(Q).$$

In a similar way, (33) and (37) lead to

$$\bar{u}_\varepsilon \longrightarrow u \text{ weakly in } L^2(Q),$$

which ends proving the announced result.  $\square$

### 3.2 Approached optimality system

Let  $\varepsilon > 0$ . Let us start by recalling that we have, for the control  $\bar{u}_\varepsilon \in \mathcal{U}_{ad}$ , optimal solution of (23), there exists

$$\bar{y}_{0\varepsilon} \in L^2(\Omega) \quad \text{and} \quad \bar{y}_\varepsilon \in L^2(Q),$$

verifying

$$\left\{ \begin{array}{l} \frac{\partial \bar{y}_\varepsilon}{\partial t} - \Delta \bar{y}_\varepsilon = \bar{u}_\varepsilon \quad \text{in } Q, \\ \bar{y}_\varepsilon = 0 \quad \text{on } \Sigma, \\ \bar{y}_\varepsilon(\cdot, 0) = \bar{y}_{0\varepsilon} \quad \text{in } \Omega, \end{array} \right.$$

and the estimate

$$\|\bar{y}_\varepsilon(\cdot, T)\|_{L^2(\Omega)} < \varepsilon.$$

So, given  $v \in \mathcal{U}_{ad}$  and  $\lambda \in \mathbb{R}^*$ ; we have:

$$\begin{aligned} J_\varepsilon(\bar{u}_\varepsilon + \lambda(v - \bar{u}_\varepsilon)) &= \frac{1}{2} \|y(\bar{u}_\varepsilon + \lambda(v - \bar{u}_\varepsilon), \bar{y}_{0\varepsilon}) - z_d\|_{L^2(Q)}^2 + \frac{N}{2} \|\bar{u}_\varepsilon + \lambda(v - \bar{u}_\varepsilon)\|_{L^2(Q)}^2 \\ &\quad + \frac{1}{2\varepsilon} \|\bar{y}_{0\varepsilon} - y(\cdot, 0)\|_{L^2(\Omega)}^2 \\ &= \frac{1}{2} \|\bar{y}_\varepsilon - z_d + \lambda\phi_\varepsilon\|_{L^2(Q)}^2 + \frac{N}{2} \|\bar{u}_\varepsilon + \lambda(v - \bar{u}_\varepsilon)\|_{L^2(Q)}^2 \\ &\quad + \frac{1}{2\varepsilon} \|\bar{y}_{0\varepsilon} - y(\cdot, 0)\|_{L^2(\Omega)}^2 \\ &= J_\varepsilon(\bar{u}_\varepsilon) + \frac{\lambda^2}{2} (\|\phi_\varepsilon\|_{L^2(Q)}^2 + N\|v - \bar{u}_\varepsilon\|_{L^2(Q)}^2) \\ &\quad + \lambda(\bar{y}_\varepsilon - z_d, \phi_\varepsilon)_{L^2(Q)} + \lambda N(\bar{u}_\varepsilon, v - \bar{u}_\varepsilon)_{L^2(Q)}, \end{aligned}$$

which gives

$$\left. \frac{d}{d\lambda} J_\varepsilon(\bar{u}_\varepsilon + \lambda(v - \bar{u}_\varepsilon)) \right|_{\lambda=0} = (\bar{y}_\varepsilon - z_d, \phi_\varepsilon)_{L^2(Q)} + N(\bar{u}_\varepsilon, v - \bar{u}_\varepsilon)_{L^2(Q)},$$

where  $\phi_\varepsilon = y(v - \bar{u}_\varepsilon, \bar{y}_{0\varepsilon}) - y(0, \bar{y}_{0\varepsilon})$  is defined by

$$\begin{cases} \frac{\partial \phi_\varepsilon}{\partial t} - \Delta \phi_\varepsilon = v - \bar{u}_\varepsilon & \text{in } Q, \\ \phi_\varepsilon = 0 & \text{on } \Sigma, \\ \phi_\varepsilon(\cdot, 0) = 0 & \text{in } \Omega. \end{cases} \quad (38)$$

Hence, we obtain with the first-order optimality condition of Euler-Lagrange that the approached optimal control  $\bar{u}_\varepsilon$  is the unique element of  $\mathcal{U}_{ad}$  satisfying

$$(\bar{y}_\varepsilon - z_d, \phi_\varepsilon)_{L^2(Q)} + N(\bar{u}_\varepsilon, v - \bar{u}_\varepsilon)_{L^2(Q)} \geq 0, \quad \forall v \in \mathcal{U}_{ad}. \quad (39)$$

Let introduce here the adjoint state  $p_\varepsilon \in L^2(Q)$  by

$$\begin{cases} -\frac{\partial p_\varepsilon}{\partial t} - \Delta p_\varepsilon = \bar{y}_\varepsilon - z_d & \text{in } Q, \\ p_\varepsilon = 0 & \text{on } \Sigma, \\ p_\varepsilon(\cdot, T) = 0 & \text{in } \Omega. \end{cases}$$

It comes with (38) that

$$-\frac{\partial p_\varepsilon}{\partial t} - \Delta p_\varepsilon = \bar{y}_\varepsilon - z_d \quad \text{in } Q$$

leads to

$$\begin{aligned} (\bar{y}_\varepsilon - z_d, \phi_\varepsilon)_{L^2(Q)} &= -\left(\frac{\partial p_\varepsilon}{\partial t}, \phi_\varepsilon\right)_{L^2(Q)} - (\Delta p_\varepsilon, \phi_\varepsilon)_{L^2(Q)} \\ &= (p_\varepsilon(\cdot, 0), \phi_\varepsilon(\cdot, 0))_{L^2(\Omega)} - (p_\varepsilon(\cdot, T), \phi_\varepsilon(\cdot, T))_{L^2(\Omega)} + \left(p_\varepsilon, \frac{\partial \phi_\varepsilon}{\partial t}\right)_{L^2(Q)} \\ &\quad - (p_\varepsilon, \Delta \phi_\varepsilon)_{L^2(Q)} - \left(\frac{\partial p_\varepsilon}{\partial \nu}, \phi_\varepsilon\right)_{L^2(\Sigma)} + \left(p_\varepsilon, \frac{\partial \phi_\varepsilon}{\partial \nu}\right)_{L^2(\Sigma)} \\ &= \left(p_\varepsilon, \frac{\partial \phi_\varepsilon}{\partial t} - \Delta \phi_\varepsilon\right)_{L^2(Q)} = (p_\varepsilon, v - \bar{u}_\varepsilon)_{L^2(Q)}, \end{aligned}$$

so that the optimality condition (39) reduces to

$$(p_\varepsilon + N\bar{u}_\varepsilon, v - \bar{u}_\varepsilon)_{L^2(Q)} \geq 0, \quad \forall v \in \mathcal{U}_{ad}.$$

We thus obtain the following result.

**Theorem 5.** *Let  $\varepsilon > 0$ . The control  $\bar{u}_\varepsilon$  is unique solution of (23) if and only if the quadruplet*

$$\{\bar{y}_{0\varepsilon}, \bar{u}_\varepsilon, \bar{y}_\varepsilon, p_\varepsilon\} \in L^2(\Omega) \times (L^2(Q))^3$$

*is solution of the approached optimality system defined by the partial differential equations systems*

$$\begin{cases} \frac{\partial \bar{y}_\varepsilon}{\partial t} - \Delta \bar{y}_\varepsilon = \bar{u}_\varepsilon & \text{in } Q, \\ \bar{y}_\varepsilon = 0 & \text{on } \Sigma, \\ \bar{y}_\varepsilon(\cdot, 0) = \bar{y}_{0\varepsilon} & \text{in } \Omega, \end{cases} \quad (40)$$

and

$$\begin{cases} -\frac{\partial p_\varepsilon}{\partial t} - \Delta p_\varepsilon = \bar{y}_\varepsilon - z_d & \text{in } Q, \\ p_\varepsilon = 0 & \text{on } \Sigma, \\ p_\varepsilon(\cdot, T) = 0 & \text{in } \Omega, \end{cases} \quad (41)$$

the estimate

$$\|\bar{y}_\varepsilon(\cdot, T)\|_{L^2(\Omega)} < \varepsilon, \quad (42)$$

and the variational inequality

$$(p_\varepsilon + N\bar{u}_\varepsilon, v - \bar{u}_\varepsilon)_{L^2(Q)} \geq 0, \quad \forall v \in \mathcal{U}_{ad}. \quad (43)$$

### 3.3 Singular optimality system

From the results obtained in Section 3.1, we have:

$$\begin{aligned} \bar{u}_\varepsilon &\longrightarrow u \text{ strongly in } L^2(Q) \\ \bar{y}_\varepsilon &\longrightarrow y \text{ strongly in } L^2(Q), \end{aligned}$$

where  $(u, y)$  is the optimal control-state pair of (20)(21)(22).

So that, (41) being well-posed in the sense of Hadamard, it follows that there exists  $p \in L^2(Q)$  such that

$$p_\varepsilon \longrightarrow p \text{ strongly in } L^2(Q).$$

Then, we easily pass the results of Theorem 5 to the limit, when  $\varepsilon \rightarrow 0$ , to obtain that the strong singular optimality system characterizing the optimal control-state pair of (20)(21)(22) is as specified below.

**Theorem 6.** *The control-state pair  $(u, y)$  is unique solution of the control problem (20)(21)(22) if and only if the triple*

$$\{u, y, p\} \in (L^2(Q))^3$$

*is solution of the singular optimality system defined by the partial differential equation systems*

$$\begin{cases} \frac{\partial y}{\partial t} - \Delta y = u & \text{in } Q, \\ y = 0 & \text{on } \Sigma, \\ y(\cdot, T) = 0 & \text{in } \Omega, \end{cases} \quad (44)$$

and

$$\begin{cases} -\frac{\partial p}{\partial t} - \Delta p = y - z_d & \text{in } Q, \\ p = 0 & \text{on } \Sigma, \\ p(\cdot, T) = 0 & \text{in } \Omega, \end{cases} \quad (45)$$

and the variational inequality

$$(p + Nu, v - u)_{L^2(Q)} \geq 0, \quad \forall v \in \mathcal{U}_{ad}. \quad (46)$$

## 4 Conclusion

In this work, we succeed in characterizing the optimal control-state pair of the control problem for the ill-posed backwards heat equation, using the controllability concept. The method consists in interpreting the initial problem as an inverse problem, we are also saying a controllability problem. An approach that allows us to obtain a strong and decoupled singular optimality system. As expected, the approach here proposed does well without using an additional assumption of the class of the regularity assumption (4) used in [1] and the Slater-type one (3). All that is required is the following

$$(u, y) : \quad y(\cdot, 0) \in L^2(\Omega). \quad (47)$$

Finally, in view of the similar results obtained for the ill-posed Cauchy system for an elliptic operator (cf. [2] and [4]), the controllability method here proposed seems relevant for control problems (of singular distributed systems) which require recourse to Slater-type assumptions such as (3).
